

Deep Learning for Time Series

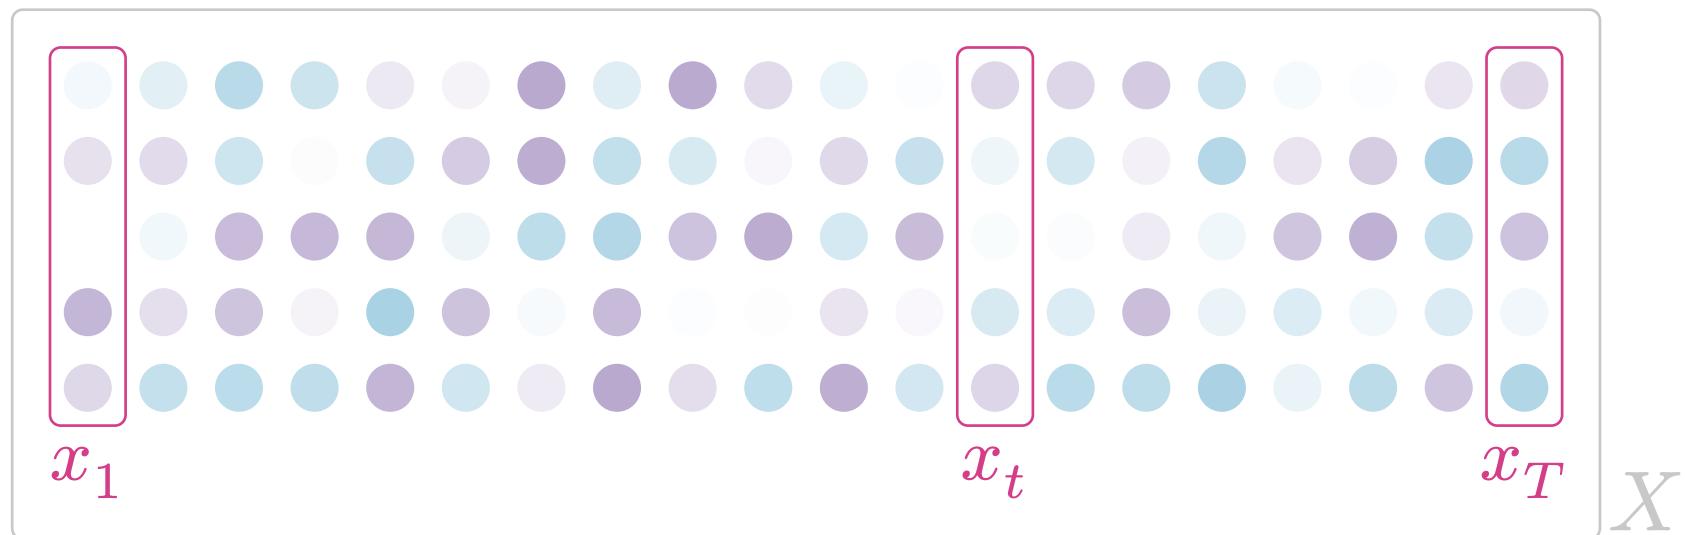

Session 1: Basics

Romain Tavenard

Definition

In this course, we will denote by *time series* any sequence of feature vectors:

$$X = (x_t)_{t=1}^T \text{ such that } x_t \in \mathbb{R}^d$$

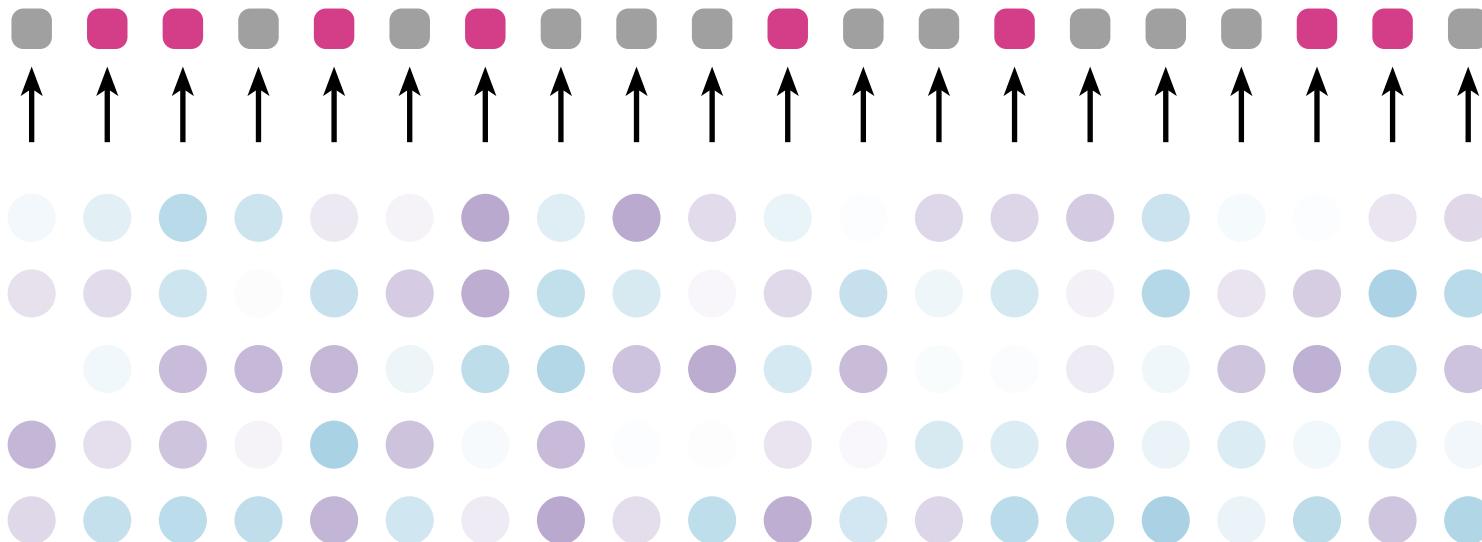

Time series tasks

Classification / labeling

Time series tasks

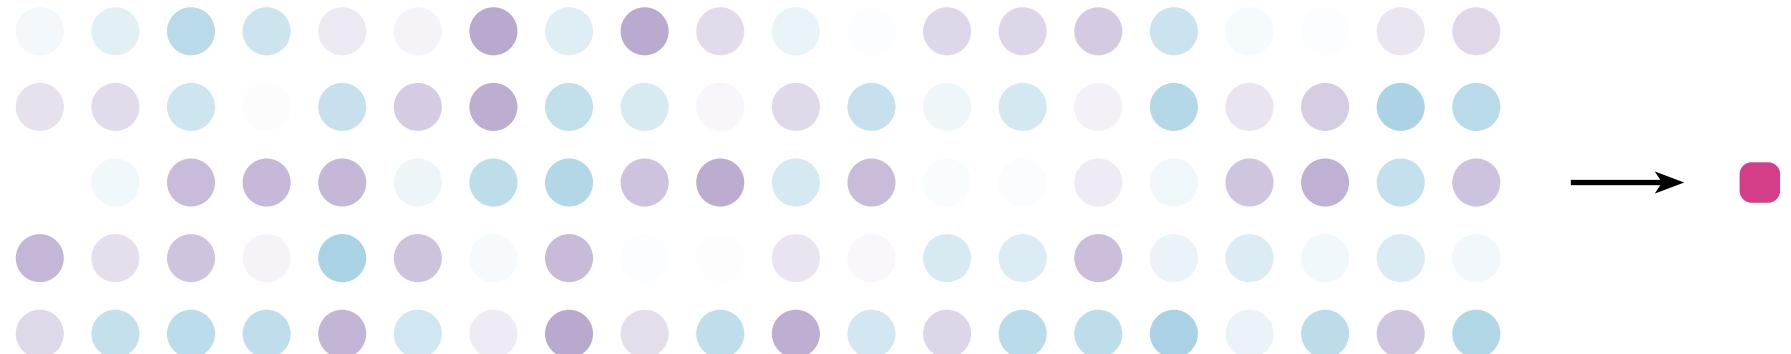

- **Labeling**

- ▶ Assign a class label to each time point (or segment)

- **Classification**

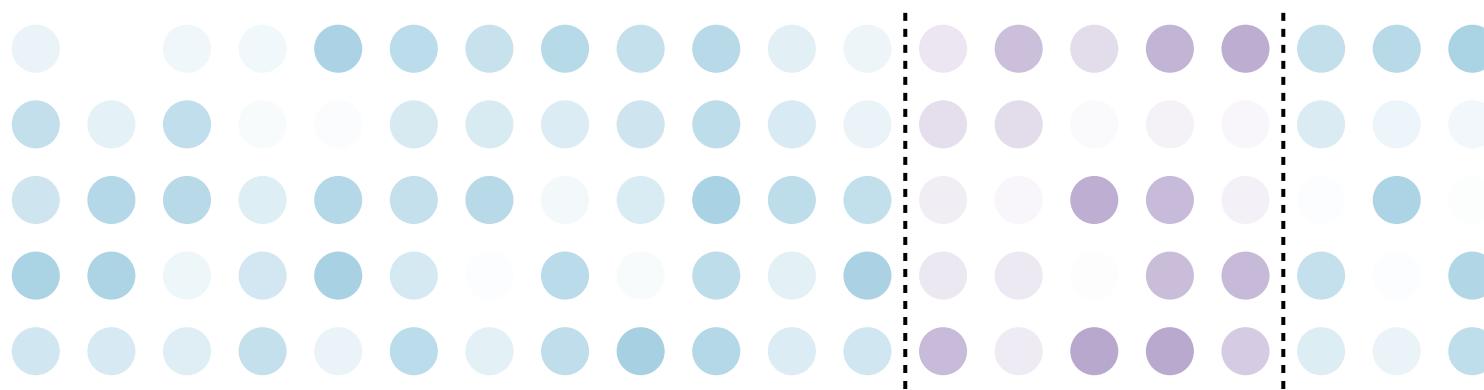

- ▶ Assign a class label to a full series

- Find unexpected points or segments
 - ▶ Usually unsupervised

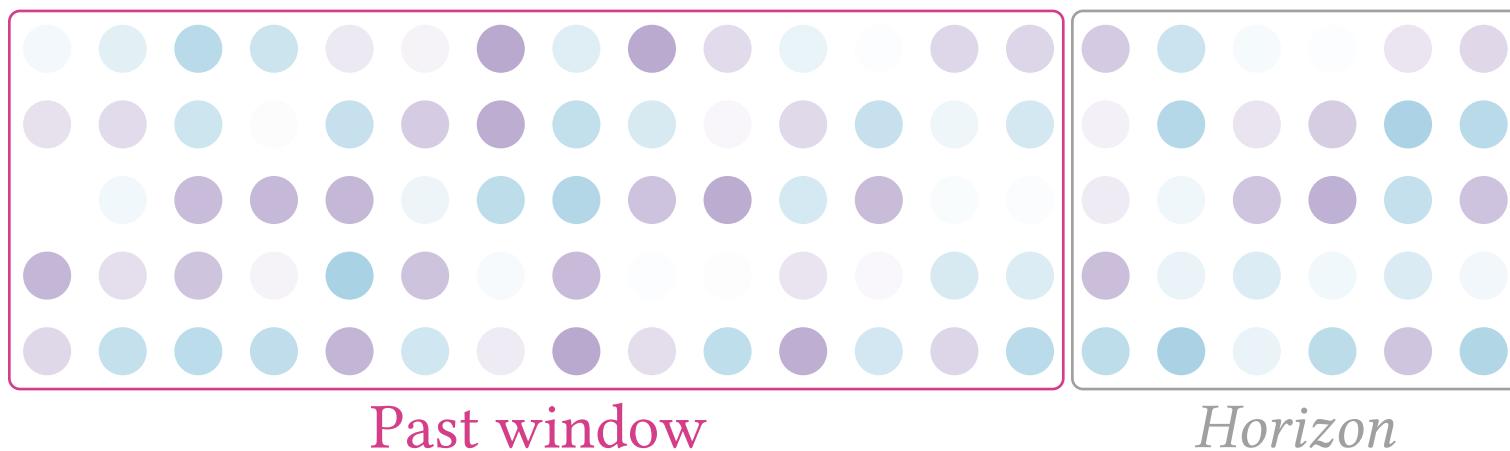

- Detect structural breaks in the sequence

- Regression task
- Target values are called **horizons**
- Model should capture temporal dependencies:

$$X_{\text{horizon}} \approx f(X_{\text{past}})$$

- ▶ Modern pipelines: forecasting is **the** pretext task for feature learning

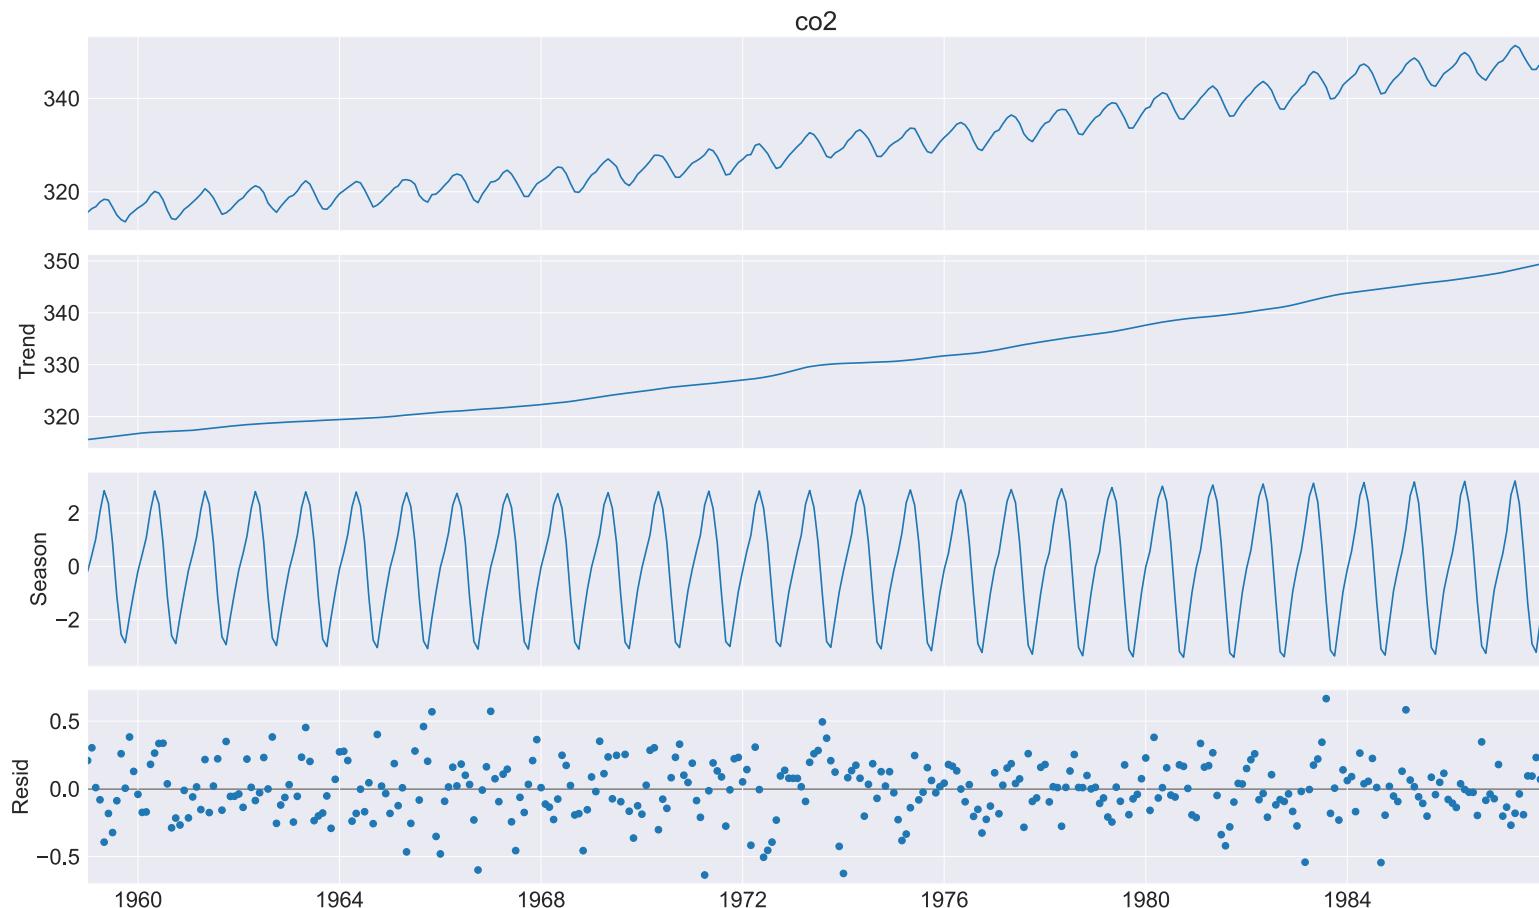

Old-school models

Additive decomposition

Old-school models

- Typical assumption: Time series can be decomposed into: Trend, Seasonality, and Residuals in an additive way:

$$x_t = T_t + S_t + R_t$$

Autoregressive AR(p)

$$x_t = c + \sum_{i=1}^p \varphi_i x_{t-i} + \varepsilon_t$$

- Linear regression model based on a window of past values of size p .
- Captures temporal correlations via lags.

Moving Average MA(q)

$$x_t = c + \sum_{j=1}^q \theta_j \varepsilon_{t-j} + \varepsilon_t$$

- Models the effect of past residuals on the current value.

ARMA(p,q)

$$x_t = c + \sum_{i=1}^p \varphi_i x_{t-i} + \sum_{j=1}^q \theta_j \varepsilon_{t-j} + \varepsilon_t$$

- Assumes stationarity.

ARIMA(p,d,q)

- Introduces differencing of order d to handle non-stationary trends.
- If $y_t = \nabla^d x_t$ (difference of order d), then y_t follows an ARMA(p,q).

Evaluation metrics and losses

Mean Squared Error MSE

$$\text{MSE}(x_t, \hat{x}_t) = \frac{1}{N} \sum_{t=1}^N \|x_t - \hat{x}_t\|_2^2$$

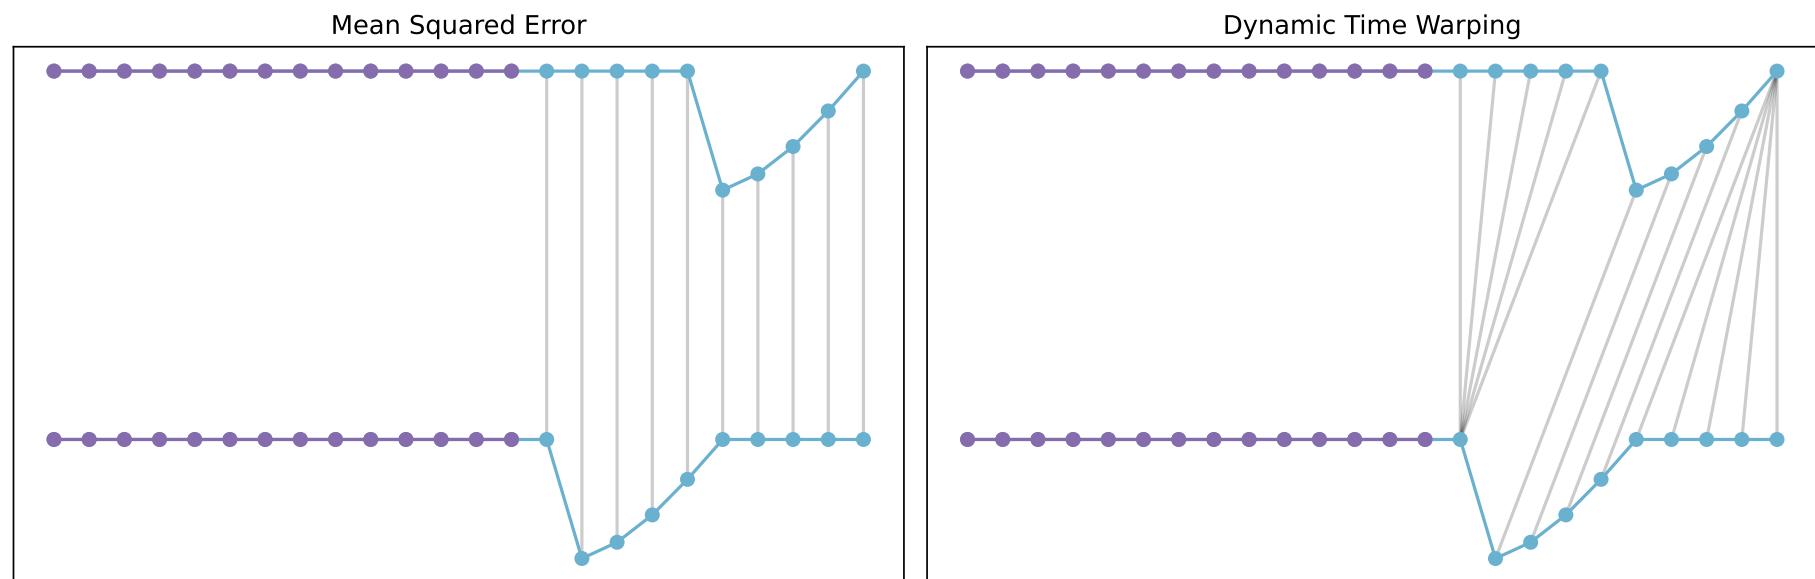

Mean Absolute Error MAE

$$\text{MAE}(x_t, \hat{x}_t) = \frac{1}{N} \sum_{t=1}^N \|x_t - \hat{x}_t\|_1$$

Symmetric Mean Absolute Percentage Error sMAPE

$$\text{sMAPE}(x_t, \hat{x}_t) = \frac{2}{N} \sum_{t=1}^N \frac{\|x_t - \hat{x}_t\|_1}{\|x_t\|_1 + \|\hat{x}_t\|_1}$$

- MSE is the *de facto* standard loss for forecasting
- Shape-based losses exist however, eg:

- Aligns two time series by warping the time axis
- Useful when similar patterns occur at different time locations
- Relies on solving the following optimization problem:

$$\text{DTW}(X, \hat{X}) = \min_{\pi \in \Pi} \sum_{t=1}^T \|x_{\pi_1(t)} - \hat{x}_{\pi_2(t)}\|_2^2$$

- Where Π is the set of all admissible alignments between the two series
- Can be solved via dynamic programming in $O(T^2)$ time

- DTW is not differentiable
- soft-DTW is a differentiable variant
- Replaces min by soft-min in the DP recursion:

$$\text{softDTW}^\gamma(X, \hat{X}) = \text{softmin}_{\pi \in \Pi}^{\gamma} \sum_{t=1}^T \|x_{\pi_1(t)} - \hat{x}_{\pi_2(t)}\|_2^2$$

- Can be used as a loss in deep learning models
- Hyperparameter $\gamma > 0$ controls the smoothness
 - $\gamma \rightarrow 0$: soft-DTW approaches DTW
 - Large γ : more smoothing (MSE-like behaviour)
